RESTORATION OF THE ABDOMINAL WALL FOLLOWING SURGERY

In many cases (up to 30% of patients), after surgery on the abdomen, the healing process can be incomplete. This may result in a Hernia or a hole in the abdominal wall that does not belong there. Types of surgery that may cause a hernia include: C-section, Intestinal Surgery, Gall Bladder Surgery, and Bariatric, or weight-loss surgery.

In many instances, a hernia may develop without having abdominal surgery. A hernia may cause pain in some persons, but not in all cases.

Some of the patients who have these defects also have a significant weight problem with considerable excess fat and skin.

A hernia may cause an unsightly bulge of the abdomen. Repairing these hernias must be done surgically and the traditional approach involves a long incision on the abdominal wall. Very often, this may be avoided by using a combined approach with an easily hidden transverse incision.

At the same time, any extra skin that may be on the abdomen is removed using the expertise of General and Reconstructive specialists.

Once the hernia(s) is repaired, the abdominal musculature will be restored to a more natural and functional state.
